Simulation study

Investigate bias from model misspecification when estimating NDE and NIE.

Simulation scenarios

Table 1: Variables used for simulations:

variable	type	true model
X(additional covariate)	continuous	$X \sim \text{gamma}(8, 4.5)$
Z(exposure)	binary	$Z = I(Y^* > 0)$ where $Z^* \sim U_0 + U_1X + N(0, 1)$
M(mediator)	continuous	$M \sim B_0 + B_1Z + B_2X + N(0, 1)$
Y(outcome)	continuous	$Y \sim \theta_0 + \theta_1Z + \theta_2M + \theta_3ZM + \theta_4X + N(0, 1)$

- $U_0 = -0.4$
- $U_1 = 0.01$
- $B_0 = 3$
- $B_1 = 2$
- $B_2 = 0.05$
- $\theta_0 = 5$
- $\theta_1 = 1$
- $\theta_2 = 0.5$
- $\theta_3 = \text{varied}[-0.5, 0.5]$
- $\theta_4 = 0.05$

Estimated mediator model was set to the correct one. Estimated outcome model was linear but misspecified without ZM interaction: $Y \sim Z + M + X$.
